# Introduction

- The prevalence of systemic mastocytosis (SM) has been estimated at up to 1 in 5,000 people<sup>1</sup>
- Indolent systemic mastocytosis (ISM), the most common subtype of SM, is a clonal mast cell (MC) disease driven by the KIT D816V mutation in ~95% of patients<sup>2–5</sup>
- Patients with ISM often experience life-long debilitating symptoms that considerably impact quality of life<sup>6–9</sup>
- These symptoms are likely due to a combination of direct MC organ infiltration, MC activation and mediator release, and inflammatory immune system alterations promoted by aberrant MCs<sup>9</sup>
- Tryptase plays an important role in inflammation and serves as a marker of MC burden and MC activation<sup>10</sup>
- Serum tryptase >20 ng/mL is a minor diagnostic criterion for SM per WHO classification.<sup>11</sup> However, ~30% of patients with ISM do not meet this criterion and baseline serum tryptase does not always correlate well with disease symptoms<sup>12</sup>
- Avapritinib is a potent, oral inhibitor that selectively targets the KIT D816V mutation,<sup>13</sup> with approximately 30-fold selectivity for the mutant KIT enzyme over the wild-type KIT enzyme<sup>14</sup>
- Avapritinib was approved in the USA and Europe for the treatment of moderate-to-severe ISM, based on the findings from the randomized, double-blind, placebo-controlled PIONEER study (NCT03731260)<sup>15,16</sup>
- To identify measurable disease-related biomarkers, we conducted high-throughput plasma proteome profiling on samples from patients with ISM enrolled in PIONEER to assess correlations between inflammatory plasma proteins and tryptase

### Figure 1. Study design

healthy donors (N=39)

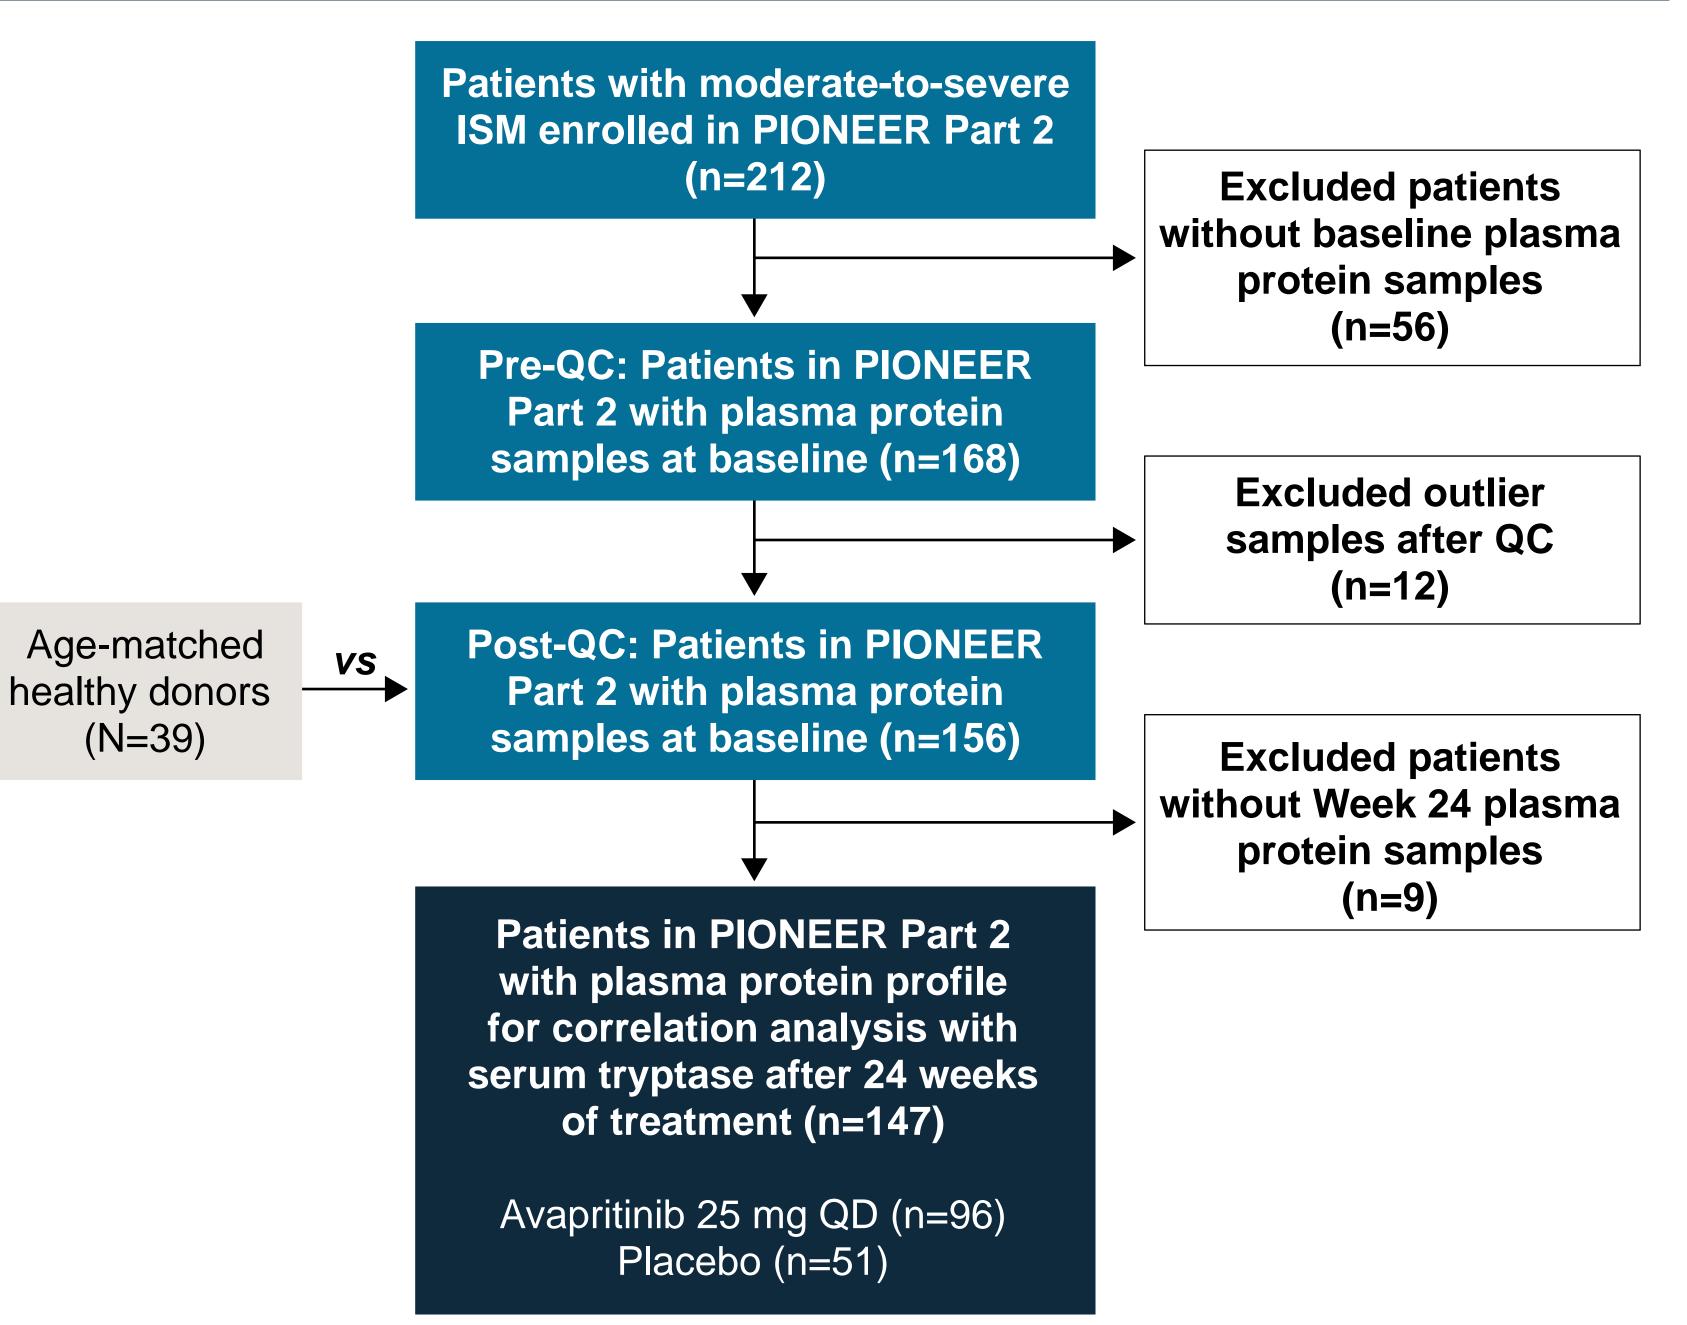

An FDR of <0.05 was considered significant</li>

### Methods

 The Olink® Explore 384 Inflammation panel (Uppsala, Sweden) measured 363 well-established inflammatory plasma proteins in plasma samples from patients in PIONEER and healthy donors (Figure 1)

# Results

- Table 1

ISM, indolent systemic mastocytosis; QC, quality control; QD, once daily.

 Plasma samples from age-matched healthy donors (n=39) were assessed as controls and compared with baseline plasma protein samples from patients in PIONEER (n=156)

Plasma protein measurements below the lower limit of quantification (LLOQ) were imputed as LLOQ values in the analysis

 Spearman's correlation coefficient (r) was determined to assess for an association between plasma proteins at baseline

 For baseline plasma protein comparison between healthy donors and patients with ISM, a t-test was performed for each protein and the resulting P-values were adjusted for multiple comparisons using the Benjamini-Hochberg method, false discovery rate (FDR)

Baseline demographics for the pooled population can be seen in

• At baseline, 156/363 proteins were significantly different in patients with ISM *versus* healthy donors (FDR < 0.05) (**Figure 2**)

### Table 1. Baseline demographics and disease characteristics

### Age (years), median (range) Female, n (%)

ISM symptom burden

Baseline ISM-SAF TSS, mean (SD)

### MC burden

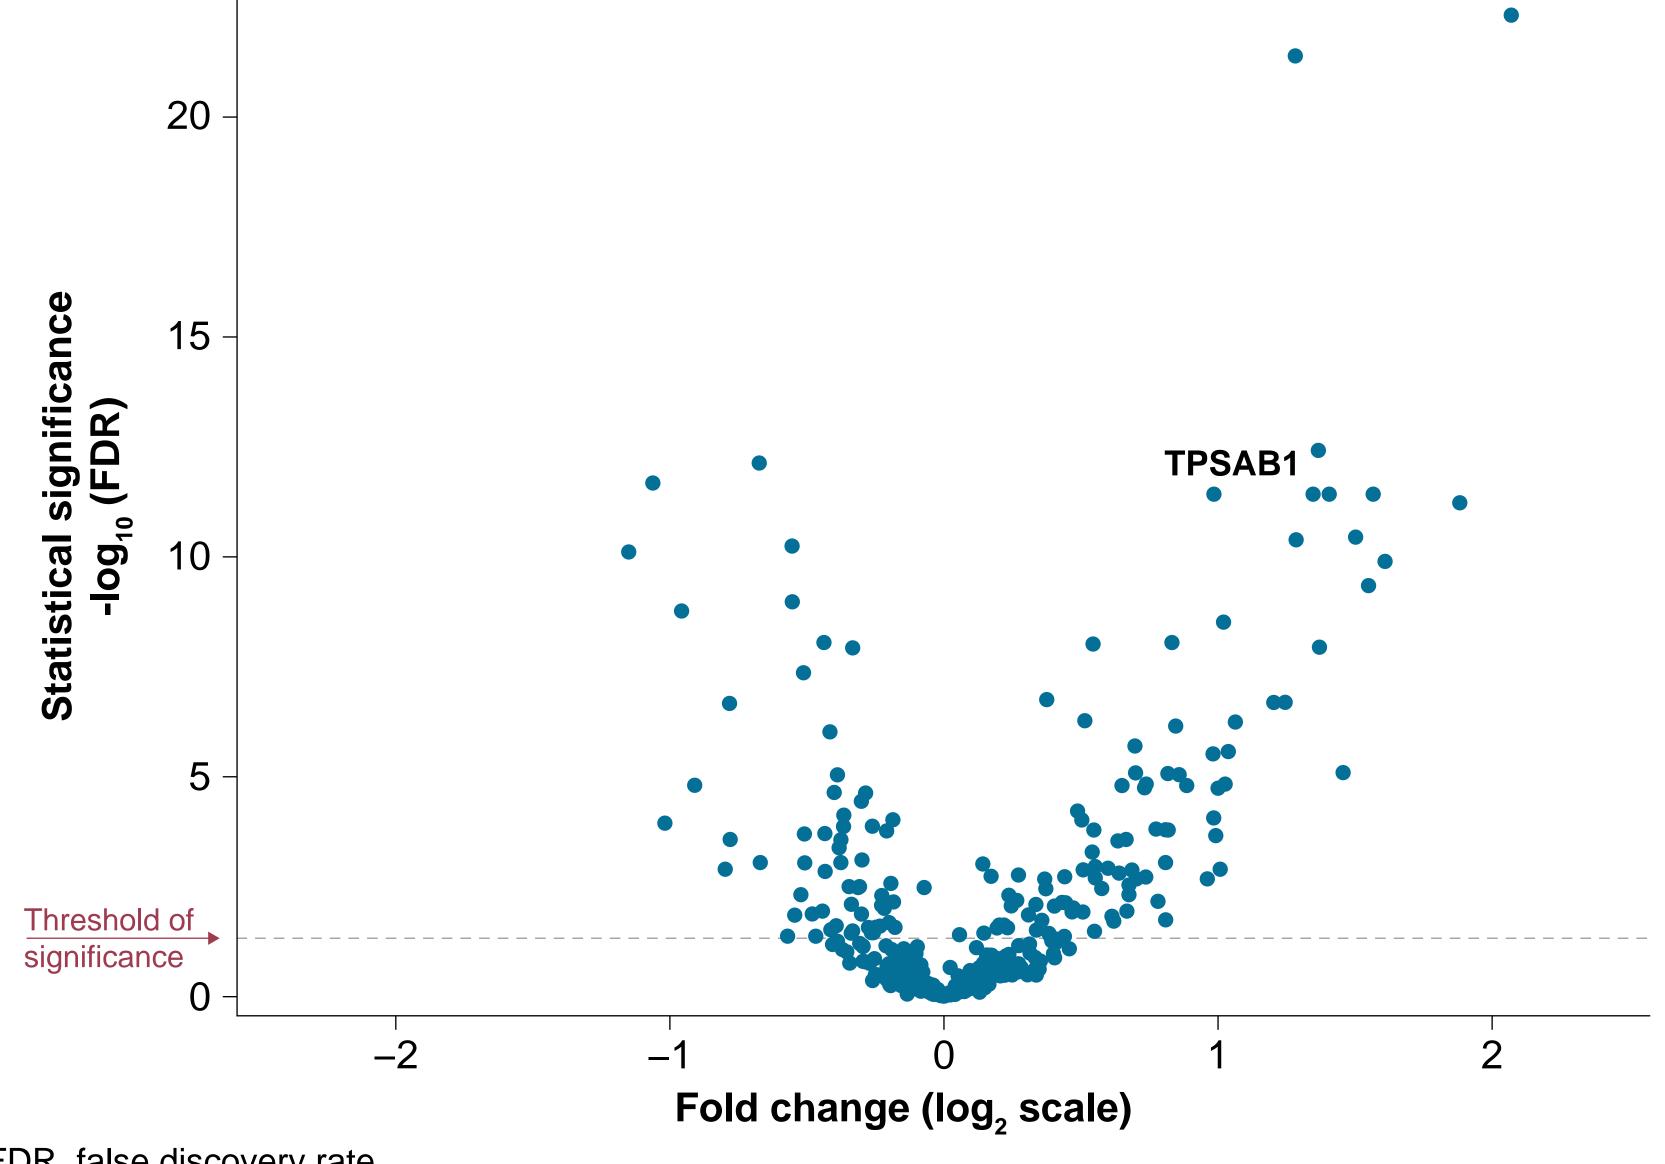

Median (range) serum tryptase (central), ng/mL

Median (range) BM MCs, %

Median (range) KIT D816V VAF in peripheral blood, %

BM, bone marrow; ISM-SAF, Indolent Systemic Mastocytosis Symptom Assessment Form (© 2018 Blueprint Medicines Corporation); MC, mast cell; SD, standard deviation; TSS, total symptom score; VAF, variant allele frequency.

### Figure 2. Comparison of plasma proteins present in **PIONEER** patients with ISM vs healthy donors

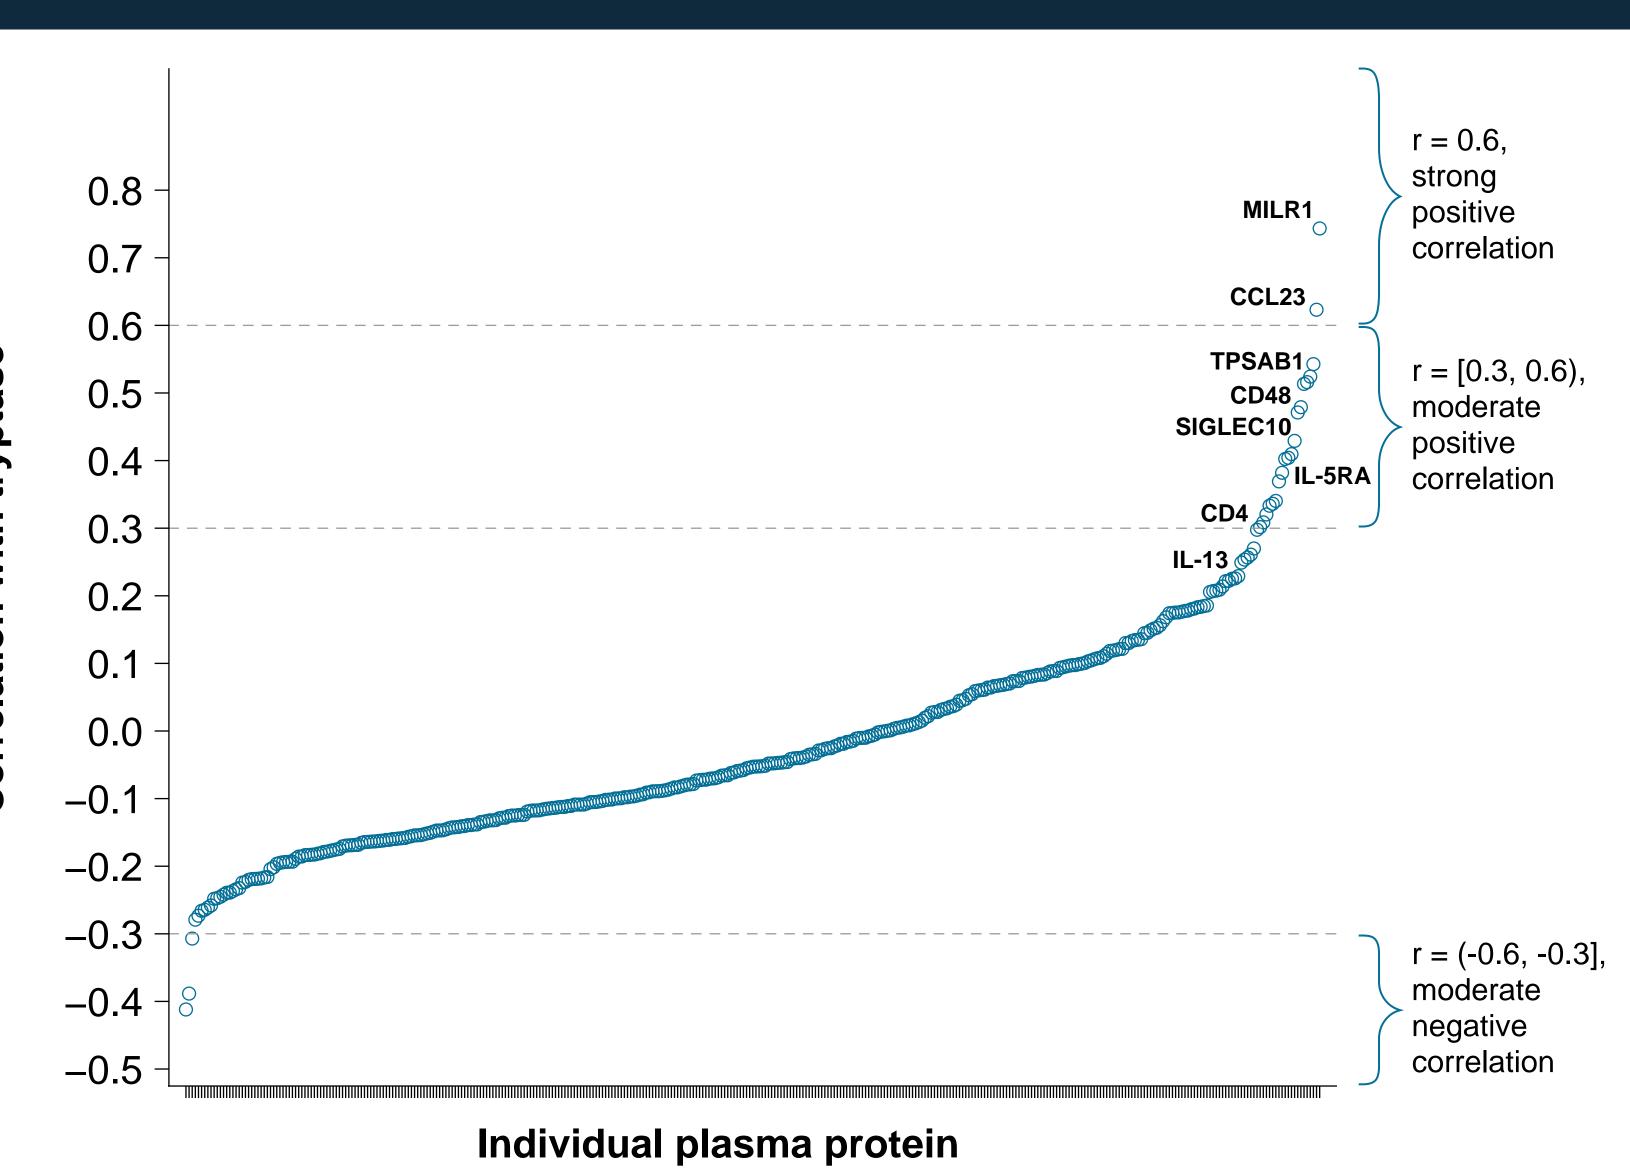

FDR, false discovery rate.

- Tryptase measured by the Olink® panel moderately correlated (r=0.52) to clinically measured serum tryptase as a positive control
- The levels of many plasma proteins also correlated with clinically measured baseline serum tryptase levels, including (r-value): MILR1 (0.74), CCL23 (0.62), CD48 (0.51), SIGLEC10 (0.43), IL-5RA (0.40), CD4 (0.30), and IL-13 (0.23) (Figure 3)

# **PIONEER** patients who received either avapritinib 25 mg QD or placebo (n=156)

	52 (22–79)	
	119 (76)	
)	51.7 (19.9)	
	44.3 (3.6–501.6)	
	7.0 (1.0–70.0)	
	0.42 (undetectable-36.7)	

### Figure 3. Correlation between baseline plasma protein Results levels and clinically measured baseline tryptase levels in patients with ISM enrolled in PIONEER Many of the proteins identified with expression patterns similar to

 Changes in serum tryptase levels with treatment were investigated, and were revealed to be significantly correlated with changes in MILR1, CCL23, CD48, and SIGLEC10 (FDR < 0.05) (Figure 4)

### Figure 4. Association of change in plasma protein levels with change in tryptase levels after 24 weeks in PIONEER

• MILR1

• CCL23

SIGLEC10

**TPSAB1** 

### - MILR1 regulates the activation of MCs<sup>17</sup> - CCL23 is produced by MCs and its levels correlate with the severity of disease, with the highest levels seen in patients with advanced SM<sup>18,19</sup>

- IL-13 is a key inflammatory cytokine in the type 2 inflammatory response, which has previously been implicated in ISM
  - pathogenesis<sup>20,2</sup> IL-5RA and associated signaling pathways play a key role in the MC – eosinophil interaction and is activated in patients with ISM<sup>22</sup>

tryptase are involved in regulating or modulating the immune system

# Conclusions

- Comprehensive plasma proteome profiling is a useful method for understanding the large-scale changes that occur in the circulating inflammatory proteome in patients with ISM
- These findings highlight aberrant inflammatory signaling pathways in ISM, raising the possibility of combination therapy with KIT D816V inhibitors to address both the MC component and the inflammatory component of this disease
- Future work will also aim to identify whether inflammatory proteome analysis can identify biomarkers that correlate with symptom severity
